Dynamic (Force) Measurement

A dynamic (force) measurement is one in which the force is changing sufficiently rapidly that the **dynamic behavior of the measuring system must be taken into account in order to achieve the desired accuracy.**

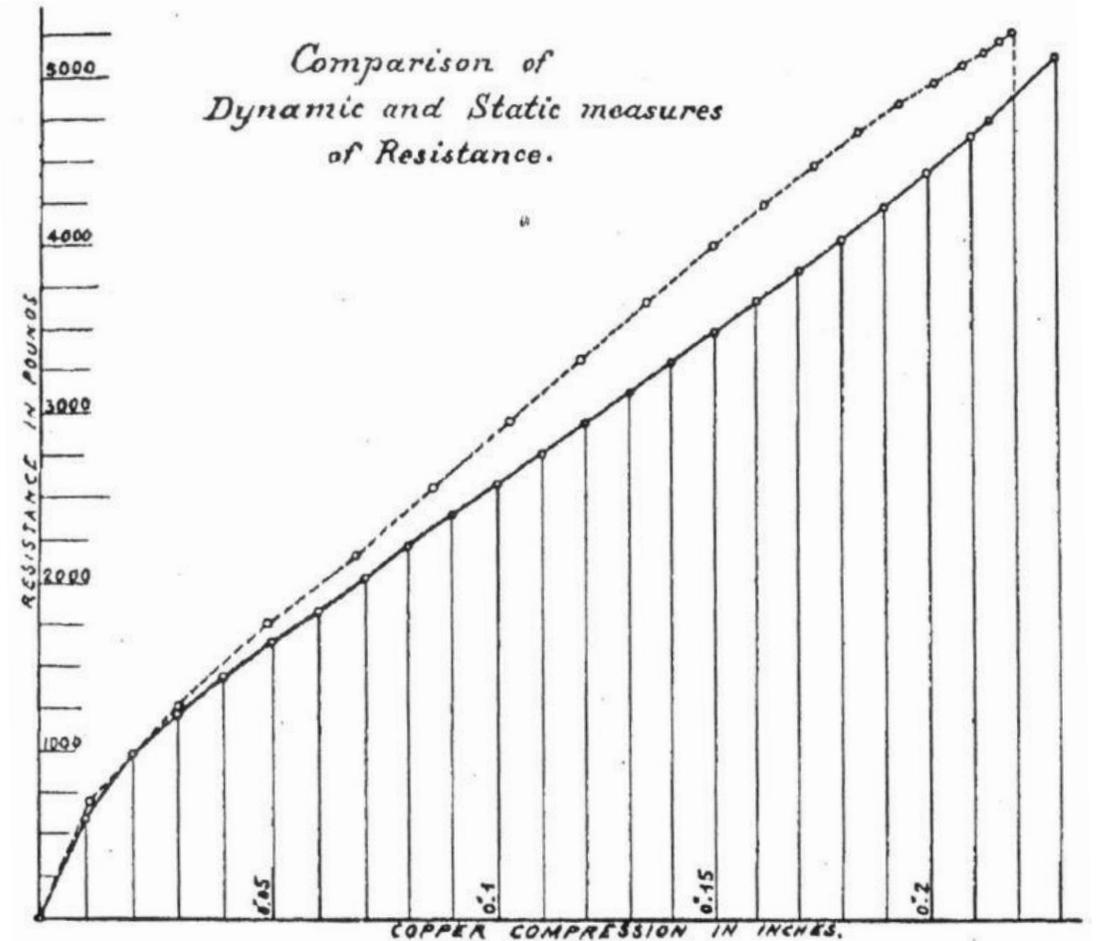

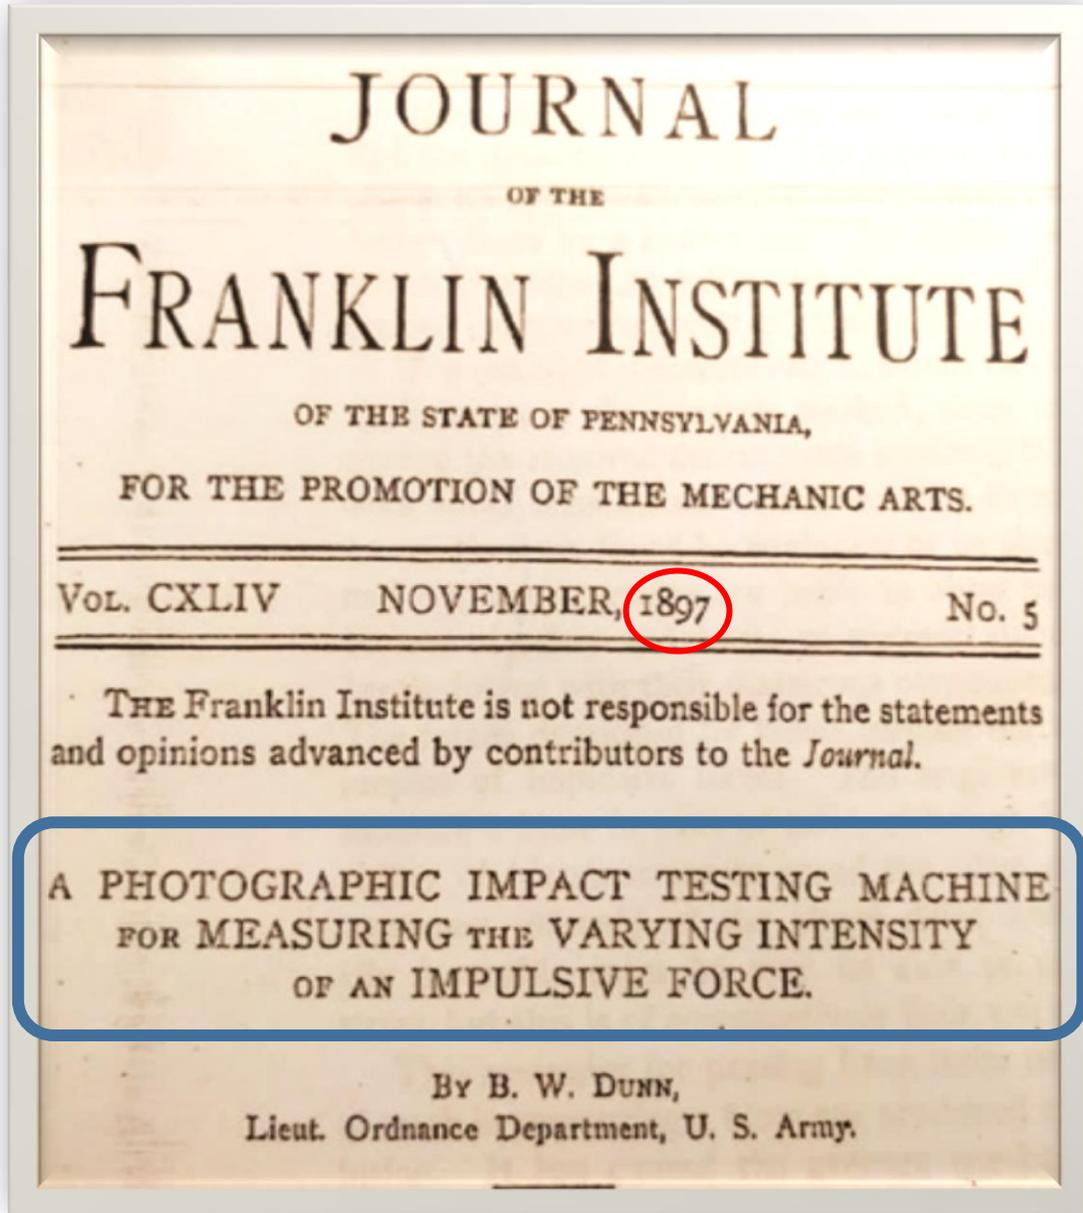

So whether a measurement must be treated as dynamic depends on:

- **The properties of the measuring system**
- **The desired accuracy**

A dynamic **(force) calibration** is a determination of the **output signal of the measurement system resulting from defined dynamic (force) inputs, with specified uncertainty.**

Ideally this would allow you to determine an unknown force input that produced a given sensor output .

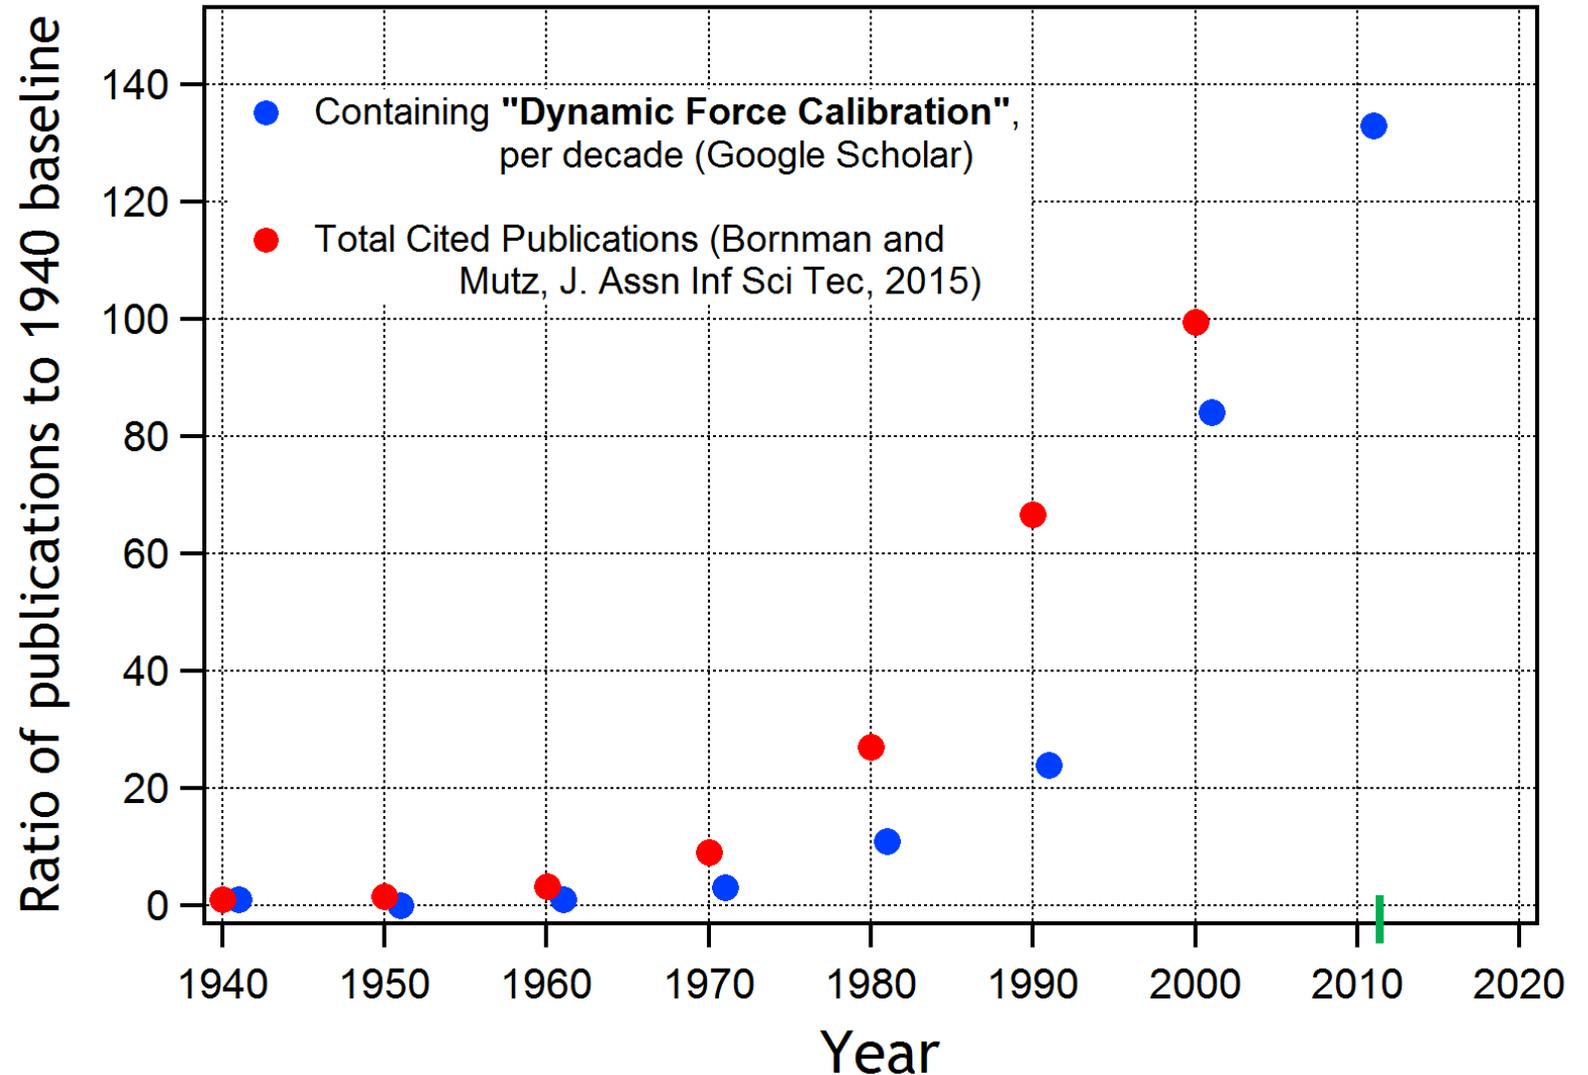

120 years ago

Impulse duration: 3 ms, Timing resolution: 2.3 μ s

More-recent activity

Low-uncertainty SI-traceable Dynamic Force

Standards

Impact standard

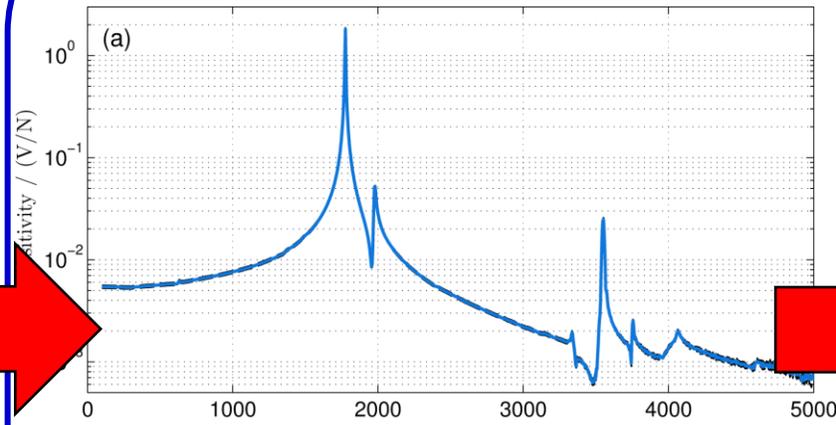

Courtesy of PTB

Shaker standard

Calibration

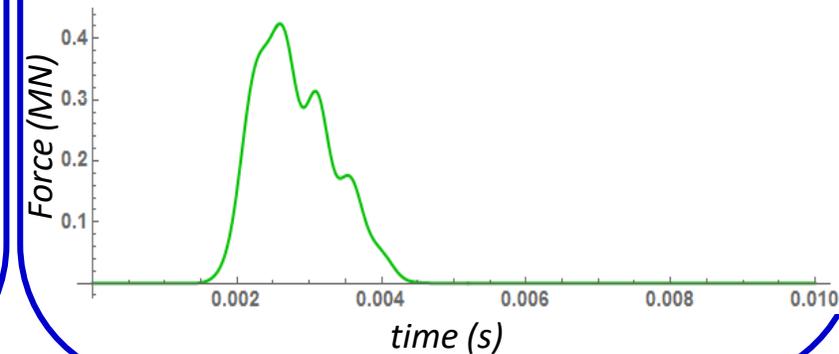

- Transfer function / impulse response (linear system)
- Model parameters describing dynamic response of the system
- Response to particular force-time profile of interest

Measurement

Courtesy of IIHS

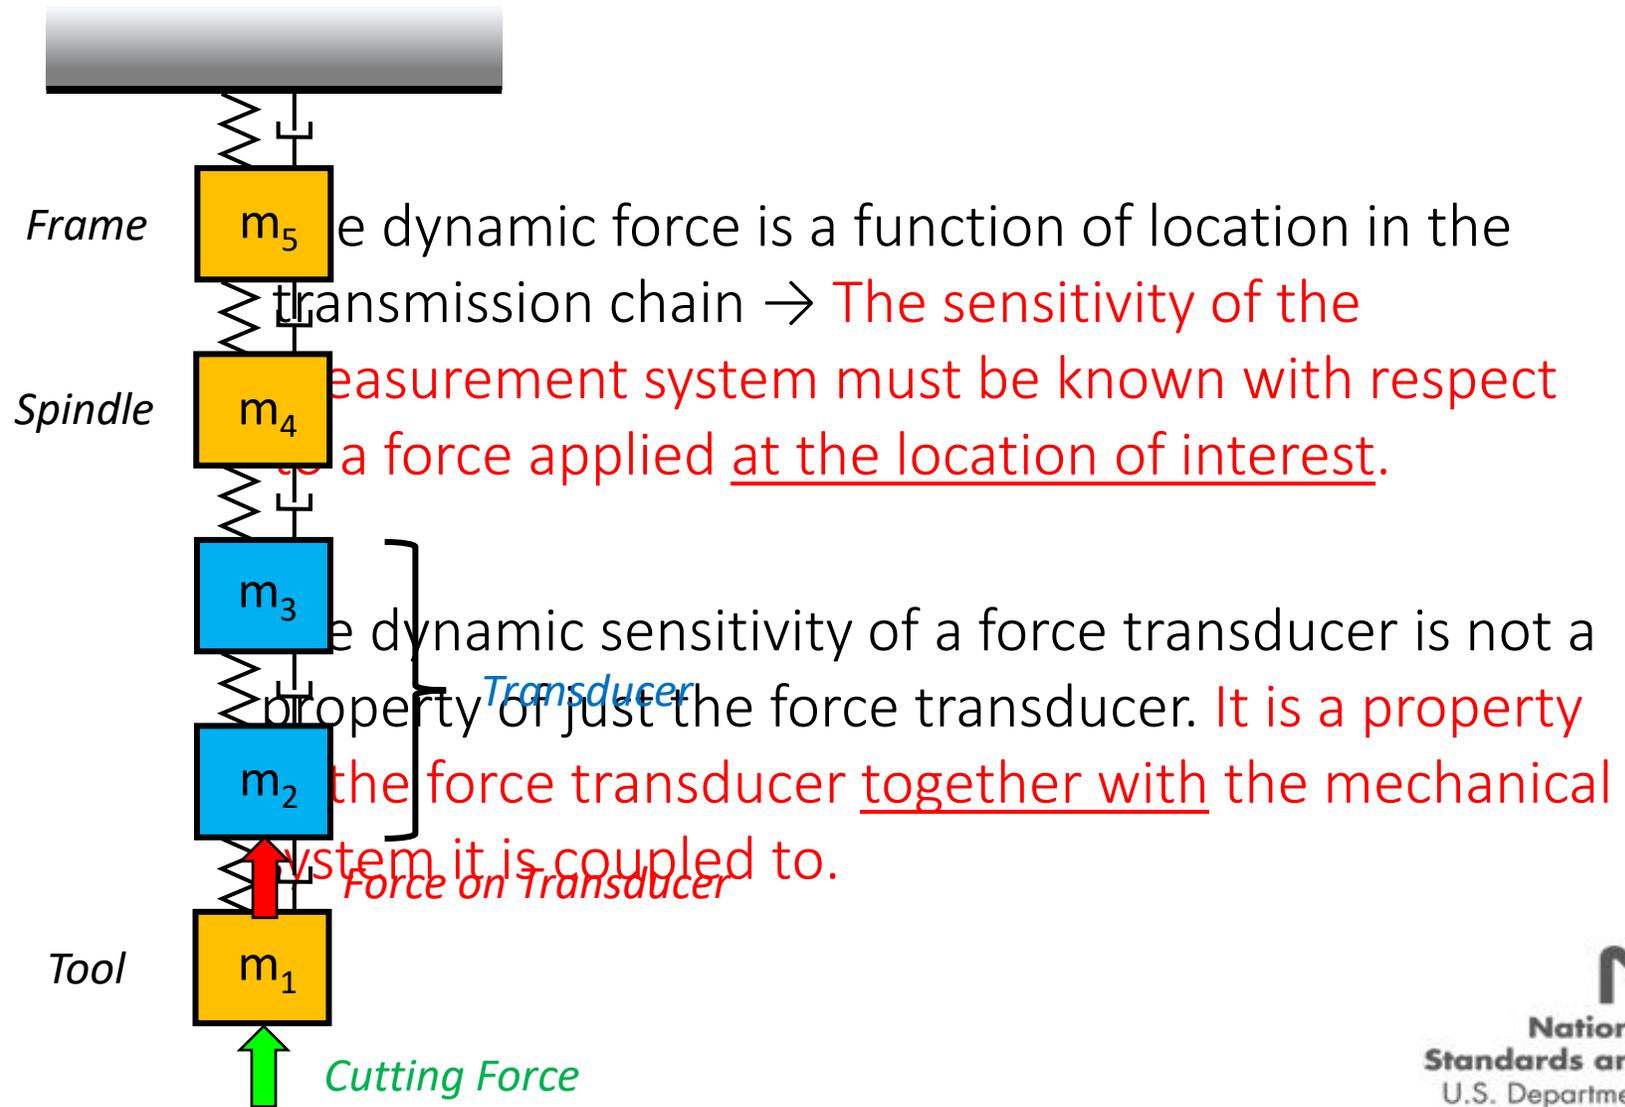

Transducer dynamic response in general changes from one setting to another, requiring (at least one of):

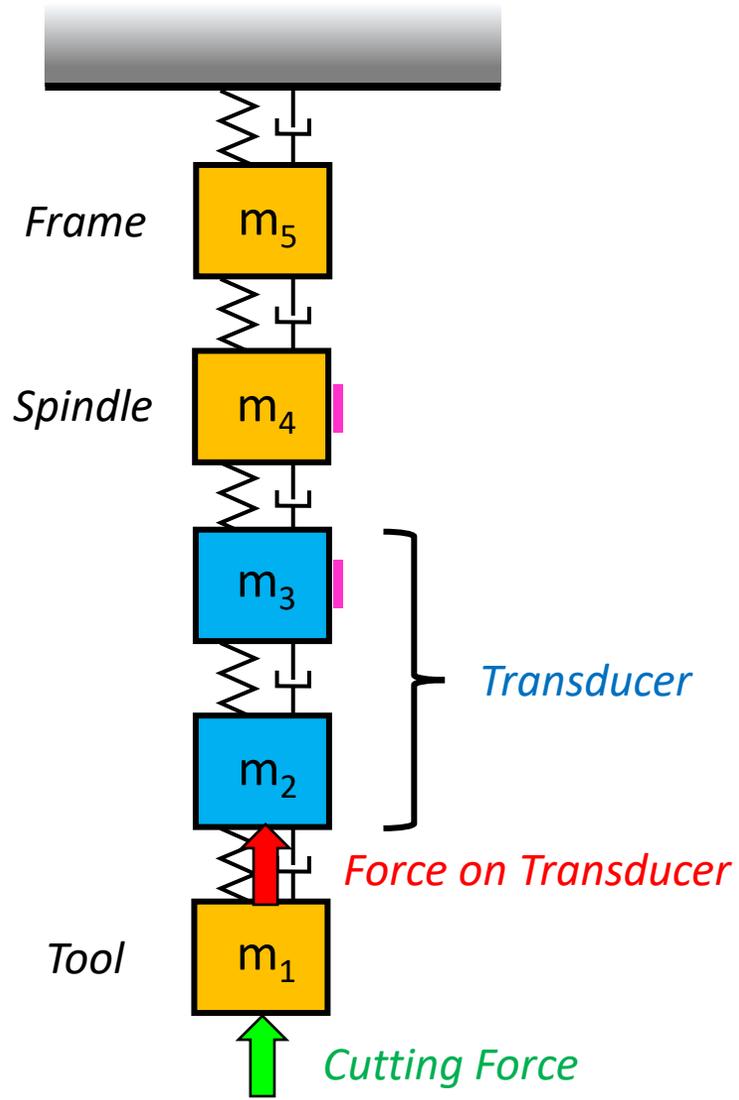

- In-situ calibration
- Model parameter calibration

Regularization is often required as the inversion is ill-posed

Challenges in Dynamic Force Measurement

One approach: Give up on using a Force Sensor

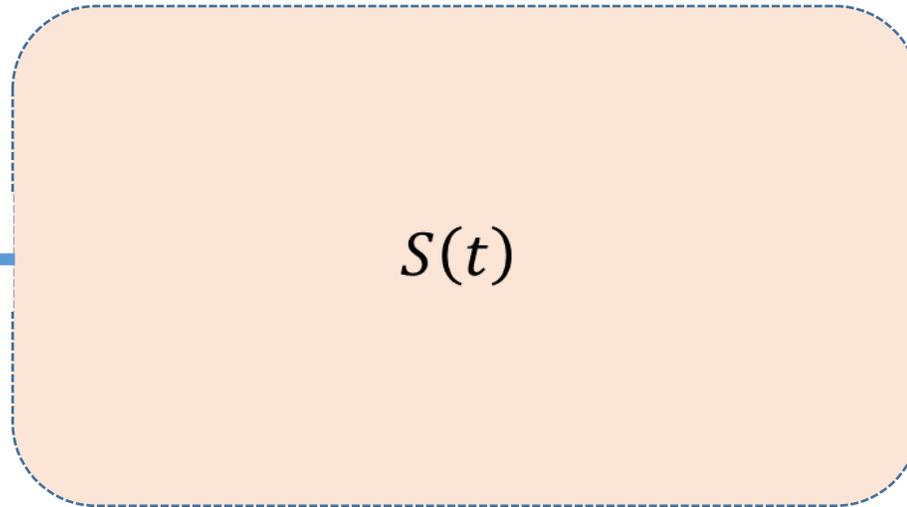

Dynamic (Force) Measurement

Input

Transducer

Output

$F(t)$

$S(t)$

$V(t)$

$$V(t) = \int_{-\infty}^{\infty} F(\tau)S(t - \tau)d\tau$$

Comparison to metrology of “fixed” mechanical quantities

Some universal similarities

- The uncertainty achieved in a calibration depends on the device being calibrated
- The uncertainty achieved in use of the device can be significantly larger than the calibration uncertainty
- Conditioning amplifiers contribute to achieved measurement uncertainty

Static force and torque metrology (**differences**)

- The force/torque applied to the device is essentially the same through the loading (train)
- Transducer sensitivity is essentially independent of the mechanical system it is used in

Mass metrology (**similarities**)

- *Dynamic methods* are used in mass metrology
- In dynamic weighing applications, there is strong overlap with dynamic force metrology
- Dynamic mass metrology in weighing of mass-changing systems (e.g. container filling)

Hardness metrology (**similarities**)

- *Dynamic methods* in hardness metrology

Comparison to metrology of other dynamic mechanical quantities

Dynamic pressure

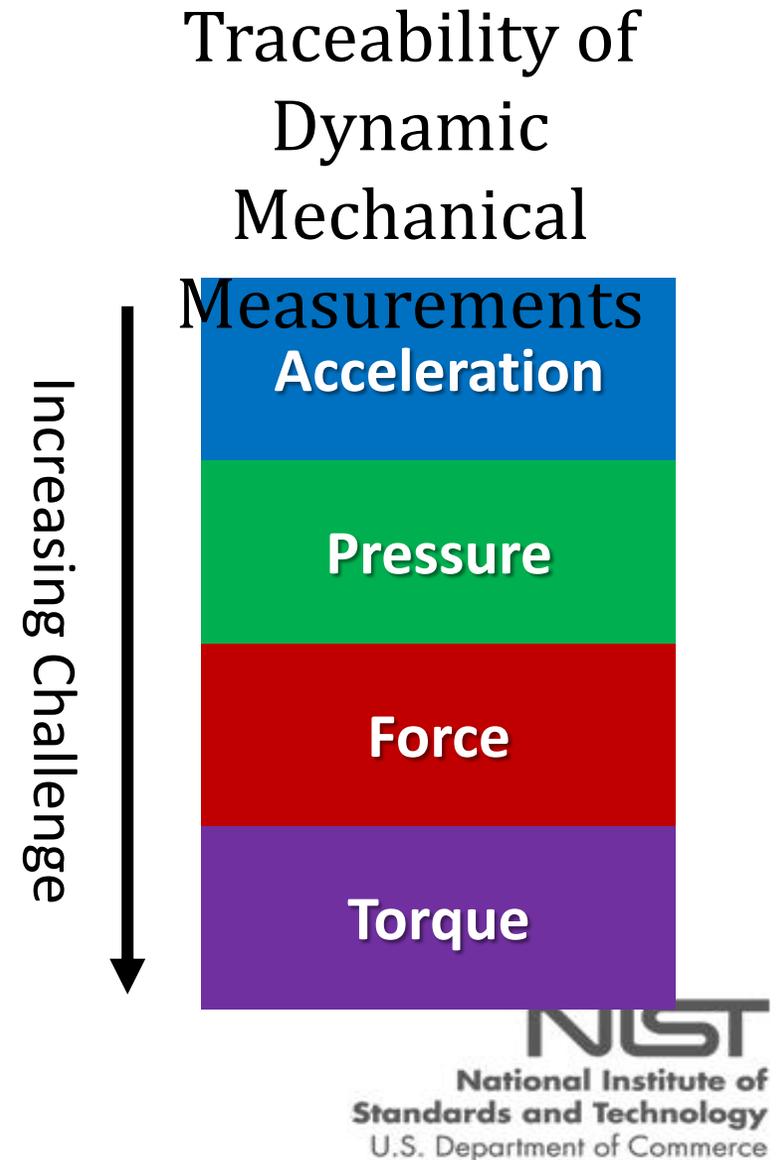

- Similar needs in calibration, modeling, and measurement uncertainty
- Need traceable standard of a generalized force variable
- The field is probed locally; the sensor does not necessarily become a critical link in the structure

Acceleration (vibration, shock)

- Similar needs in modeling and measurement uncertainty
- For shock: Similar needs in dynamic calibration
- Vibration calibration well established
- Generalized displacement variable

Dynamic torque

- All the same considerations as for dynamic force calibration apply, with the additional complications of a moment arm.

Outline

Overview and (some) History

Application Examples

- Charpy Impact Testing
- Unsteady Aerodynamics

NMI Facilities and Activities

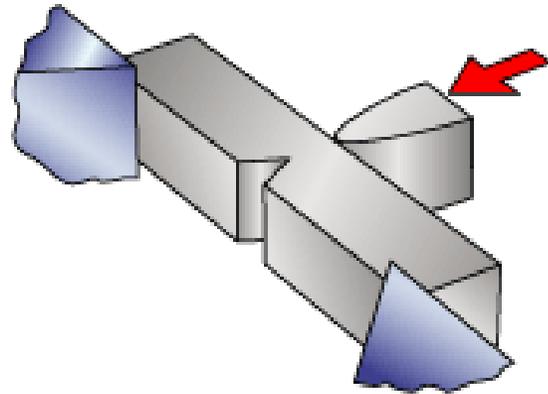

Charpy Impact Testing

Primary method used to qualify notch toughness of metals

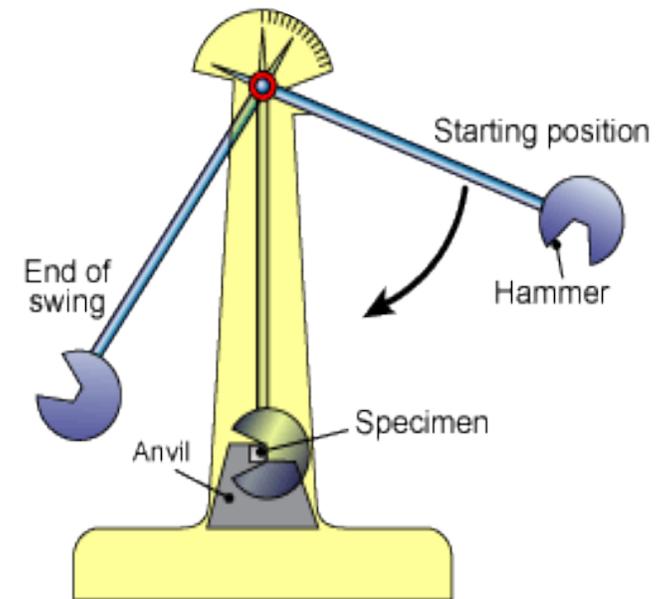

Automotive, ship, rails, nuclear reactor containment, cryogenic containers, aerospace, buildings...

- Attributed to S. B. Russell (1898) and M. G. Charpy (1901).

Measures the energy absorbed in fracturing a notched specimen

Images courtesy of TWI

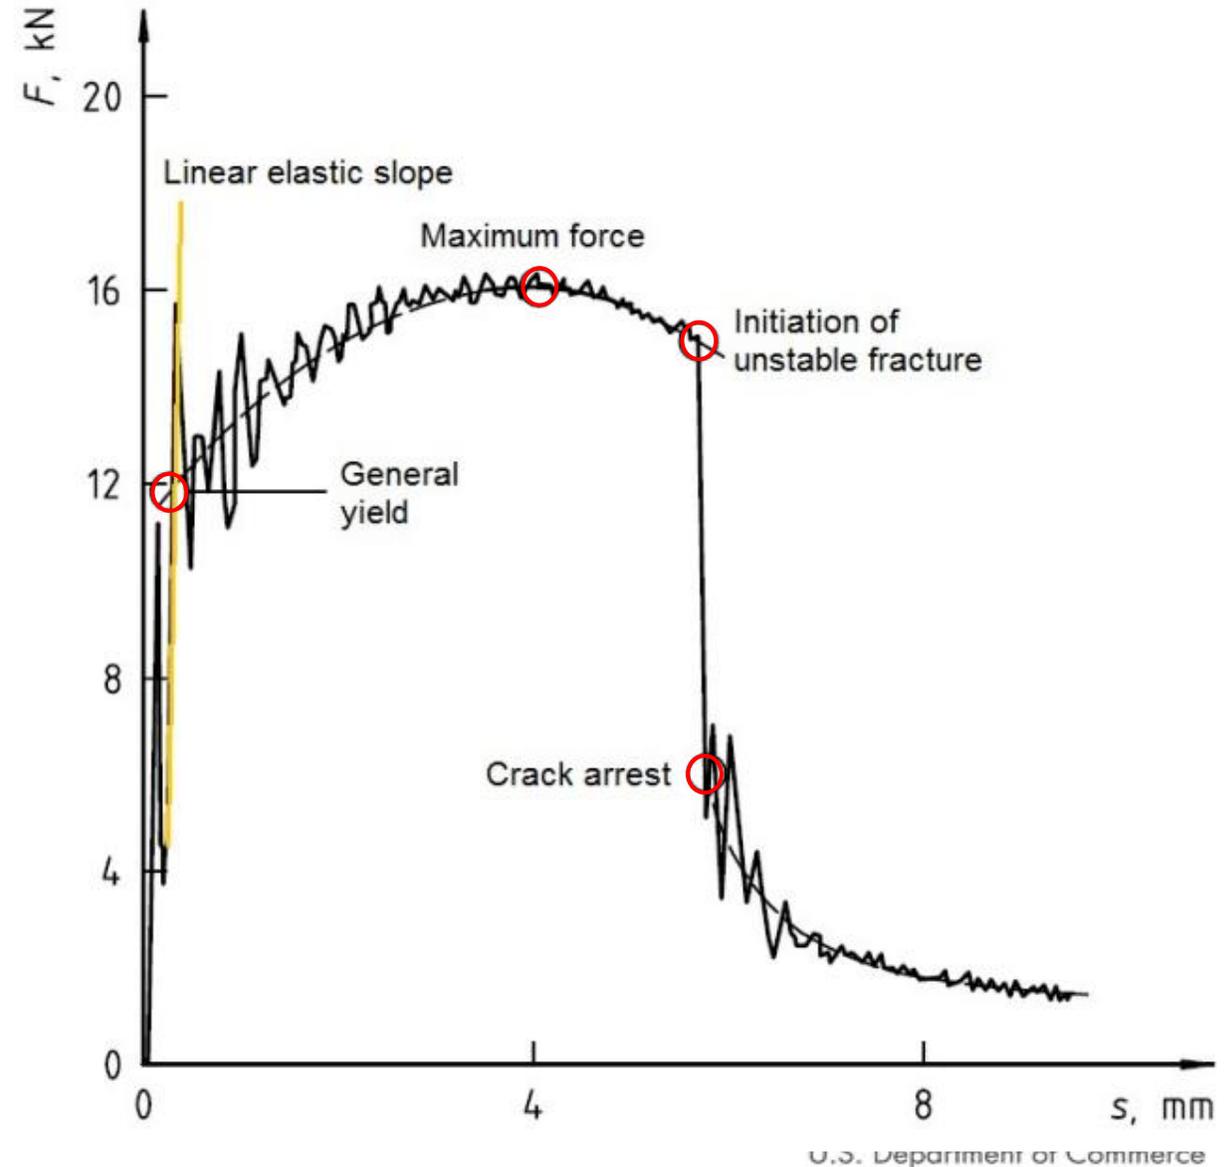

- NIST Charpy Machine Verification Program has established tightest agreement among any population of Charpy machines in the world

Instrumented Charpy Impact Testing

From the early days of Charpy testing, it has been desired to measure not only the absorbed energy but also the applied force profile, but the latter is significantly more challenging than the former.

Extracted information

- Dynamic yield strength
- Dynamic tensile strength
- Dynamic fracture toughness
- Fracture arrest load

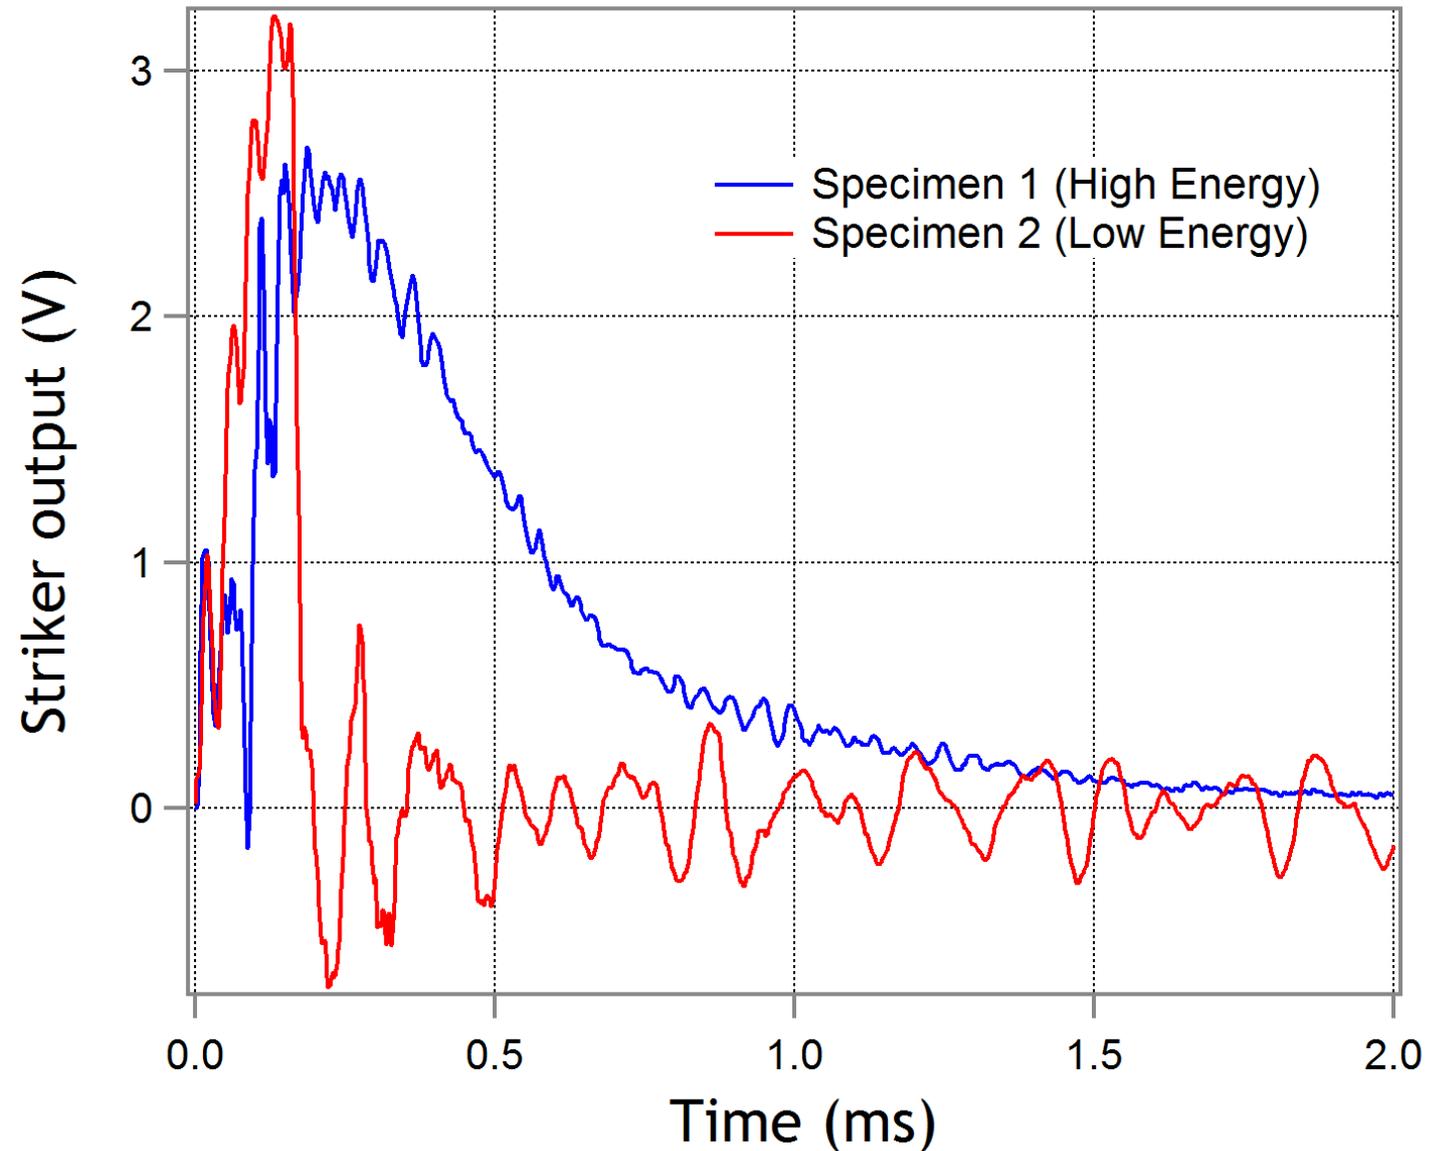

Instrumented Charpy Impact Testing – Striker Calibration

Static Calibration (usual)

Ex-situ or In-Situ

Dynamic methods investigated

- Integrate **force-displacement** to get **energy**, and scale the force values to give agreement with the absorbed energy measurement.
- Calibrate by impact with a mounted force transducer (low blow)
- Instrumented hammer
- Impacting mass

Unsteady Aerodynamics

Some Types of Demonstrated Dynamic Force Standards

“Calibration” without dynamic force standards

Modeling, in the form of some assumptions, is a feature of most dynamic calibrations, and provides

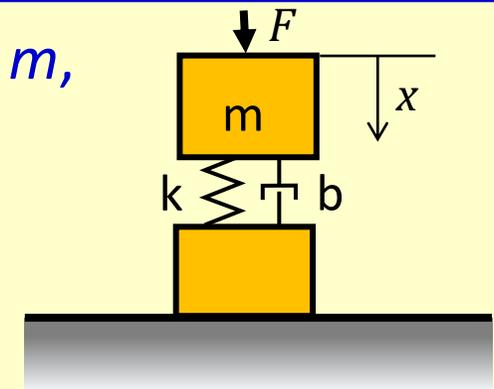

- communication of calibration results and incorporation of them into a larger system
- reduces the requirement on the force standard
- means of inversion and determination of measurement uncertainty

In general the uncertainty depends on both the uncertainty of the model parameters and the degree of applicability of the model.

It can be the case that a model (e.g. parameter values) are not determined using known dynamic forces applied over the range of interest.

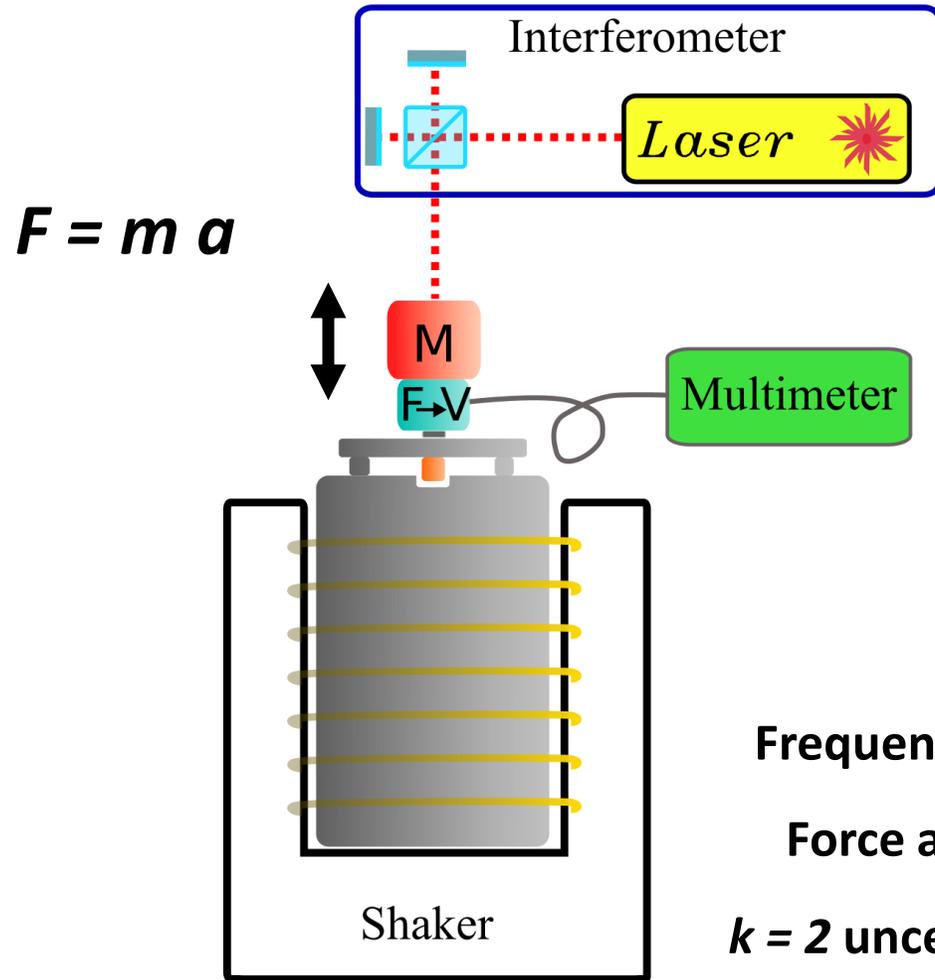

Example: Simple harmonic oscillator model with parameters m , k , b determined by static loading (k) and by a tap test (m , b).

$$m\ddot{x}(t) + b\dot{x}(t) + kx(t) = F(t)$$

If the validity of the developed model is not tested by applying known dynamic force inputs adequately covering the range of interest, then I would not call it a calibration.

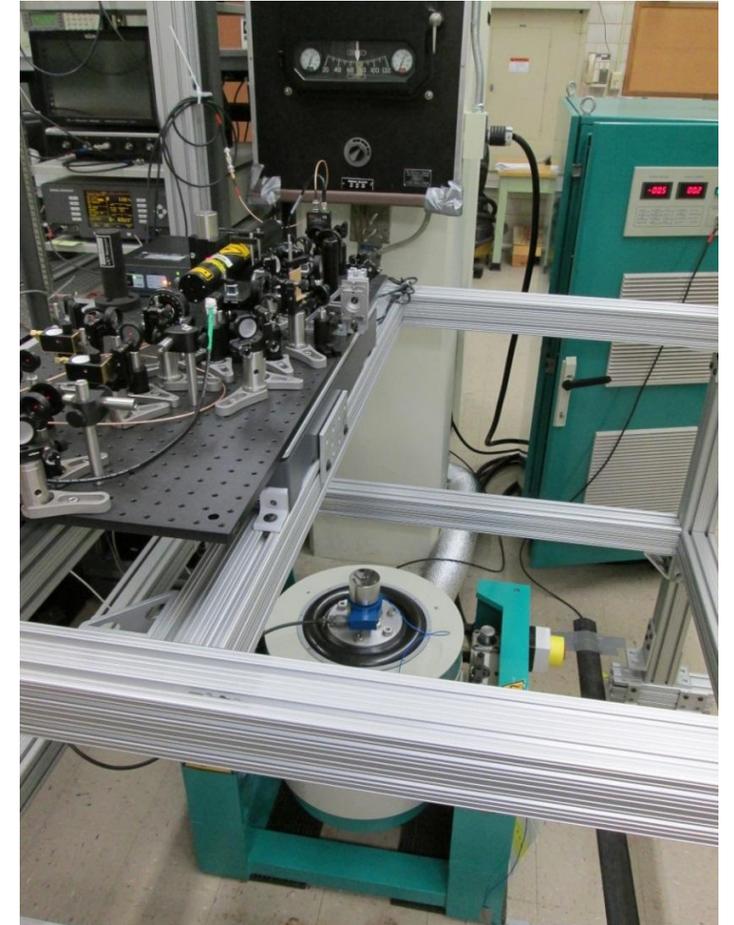

NIST Shaker-driven dynamic force standard

Frequency (sinusoidal) up to 2 kHz

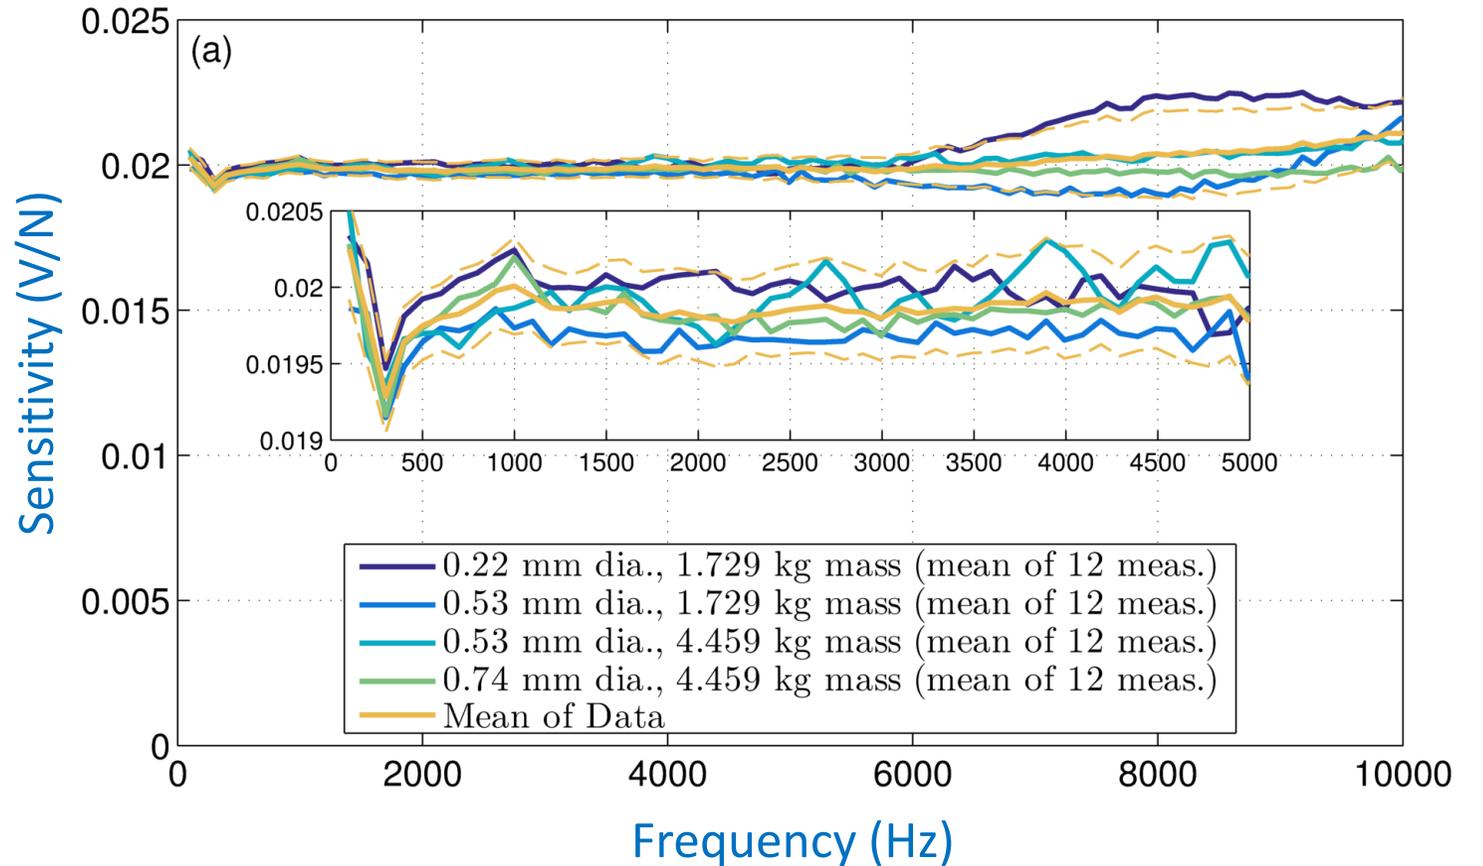

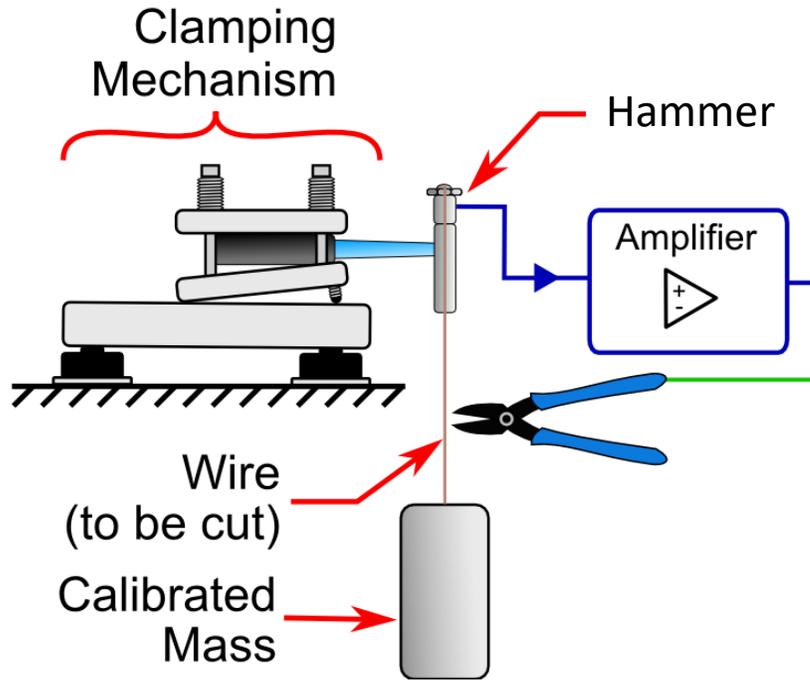

Force amplitude up to 1.5 kN

$k = 2$ uncertainty range 0.10 % - 3.0 %

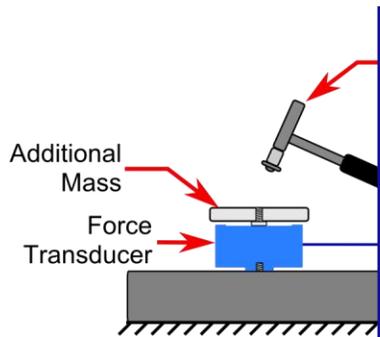

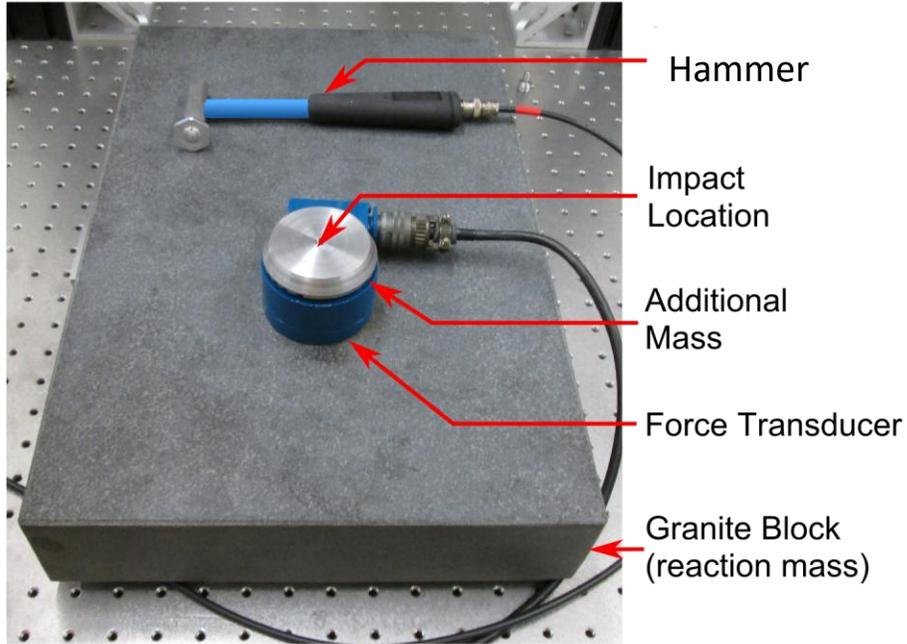

Force application from 100 Hz - 2 kHz with $k = 2$ uncertainty < 1.5 %

NIST Instrumented Hammer Calibration Test

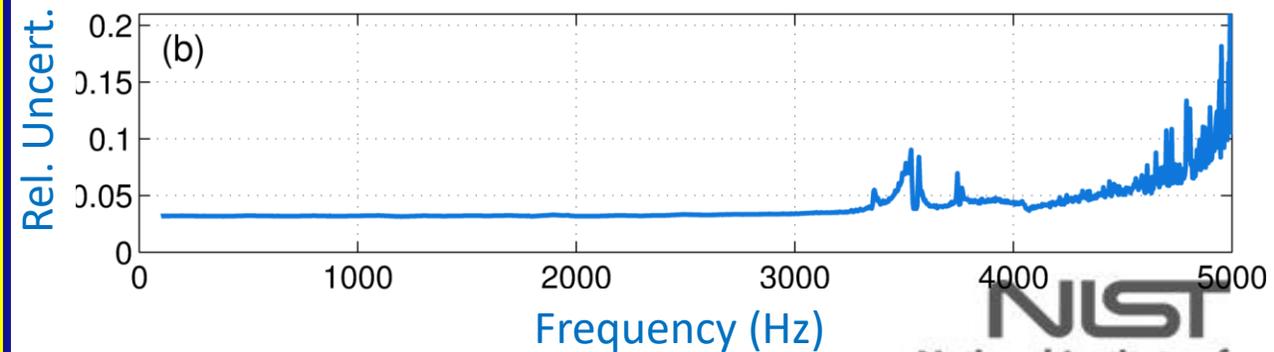

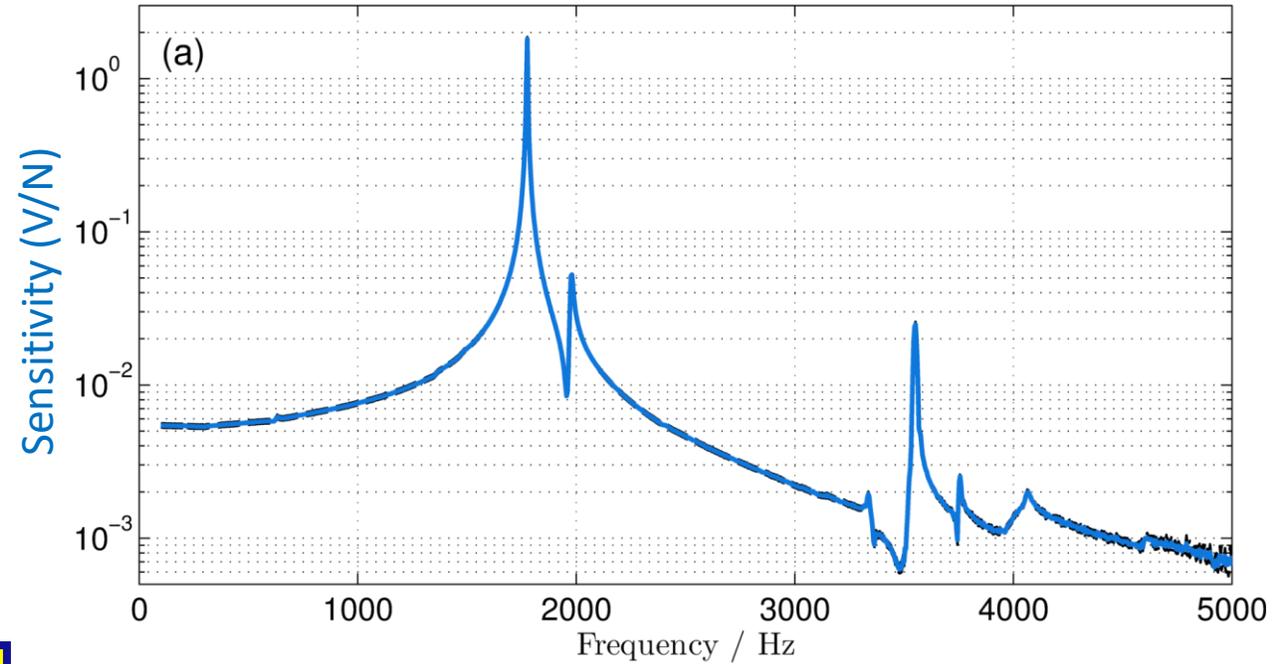

$k = 2$ uncertainty < 2.1 % up to 5 kHz

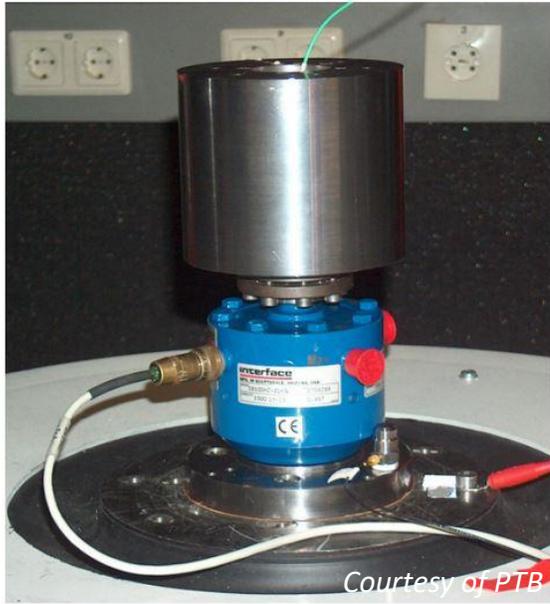

NIST Instrumented Hammer Calibration Test

- ❖ Force does not need to be explicitly determined.
- ❖ Voltage measurement in transfer does not need to be traceable

Availability of low-uncertainty dynamic force standards

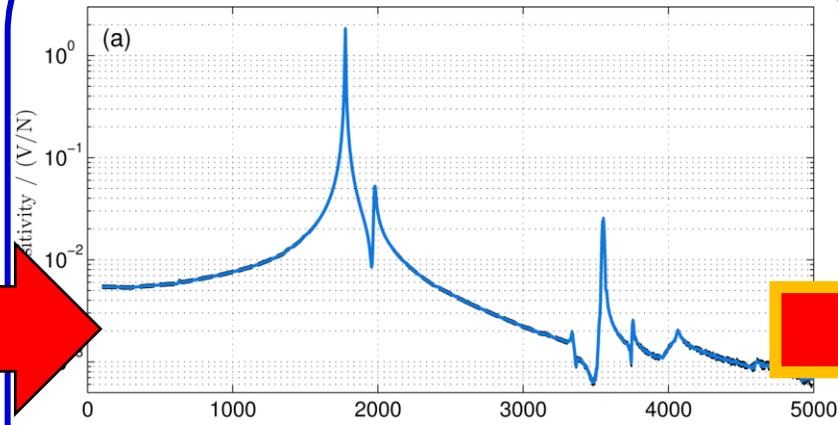

Going from dynamic calibration to dynamic measurement

Standards

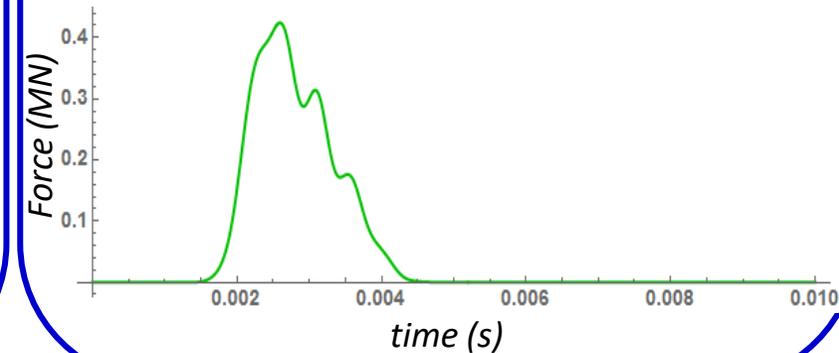

Calibration

- Transfer function / impulse response (linear system)
- Model parameters describing dynamic response of the system
- Response to particular force-time profile of interest

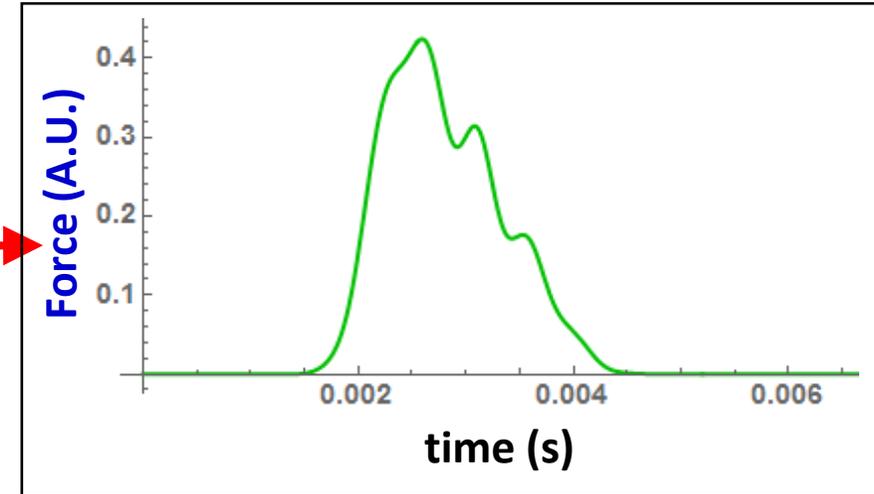

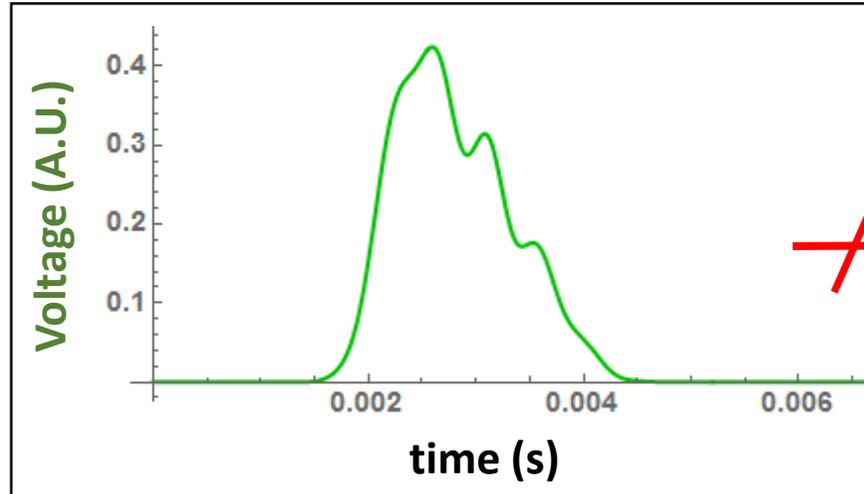

Measurement

Going from dynamic calibration to dynamic measurement

There is **not** proportionality between output signal (e.g. voltage) and the input force, as a function of time:

$$V(t) = \int_{-\infty}^{\infty} F(\tau)S(t - \tau)d\tau$$

In the frequency domain, for a linear time-invariant system, there is proportionality

$$V(s) = F(s)S(s)$$

Various methods to deconvolve (invert) are available in time, frequency domains. However the problem is *ill-posed*: insufficient signal-to-noise will lead to large errors in the deconvolved force.

Going from dynamic calibration to dynamic measurement

Challenge 1: “Regularization” to make the inversion stable ✓

Many techniques are available to regularize, in time, frequency domains

Challenge 2: Quantifying the uncertainty of the deconvolved input (force)

Conclusion: Status of Dynamic Force Metrology

Are SI-traceable dynamic force measurements with quantified, low uncertainties ubiquitously available?

No. Not yet.

Are SI-traceable dynamic force measurements with quantified, low uncertainties possible?

Yes. At least sometimes.

Are SI-traceable dynamic force measurements with quantified, low uncertainties widely available?

Yes, sometimes.

Are SI-traceable dynamic force measurements with quantified, low uncertainties sometimes impossible?

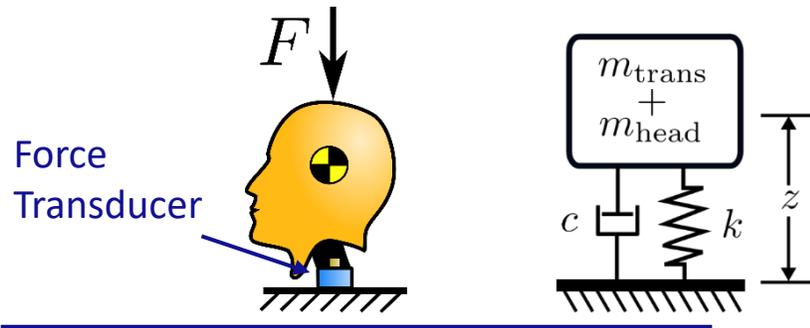

Currently, yes.

Progress is being made!

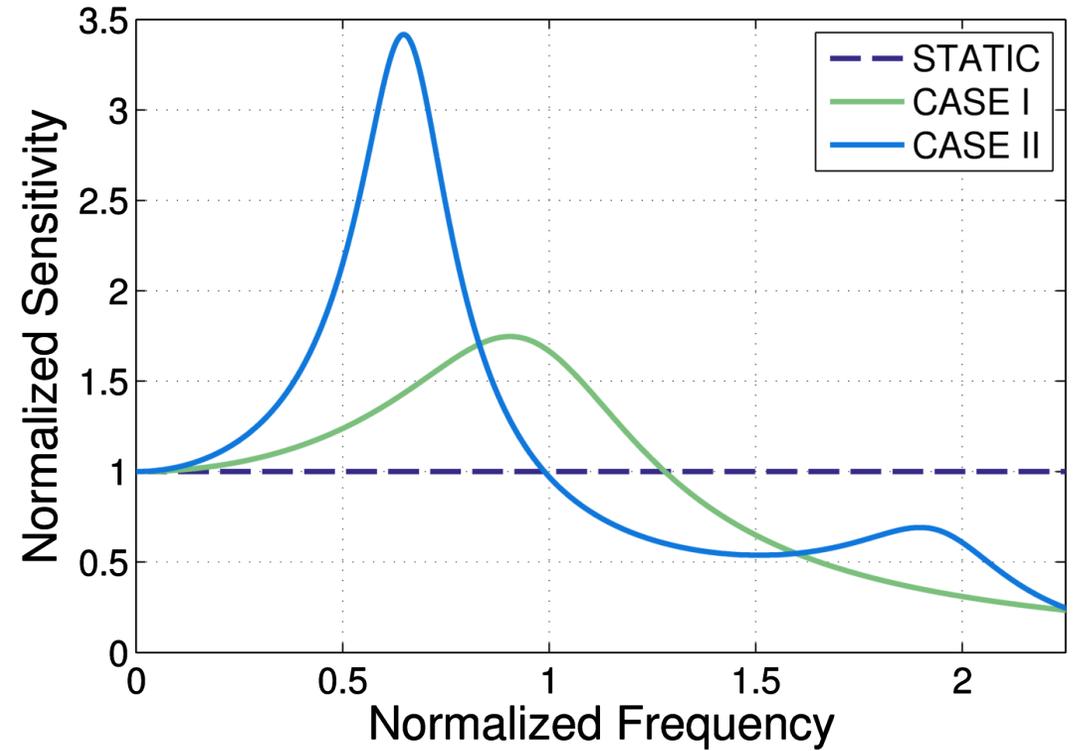

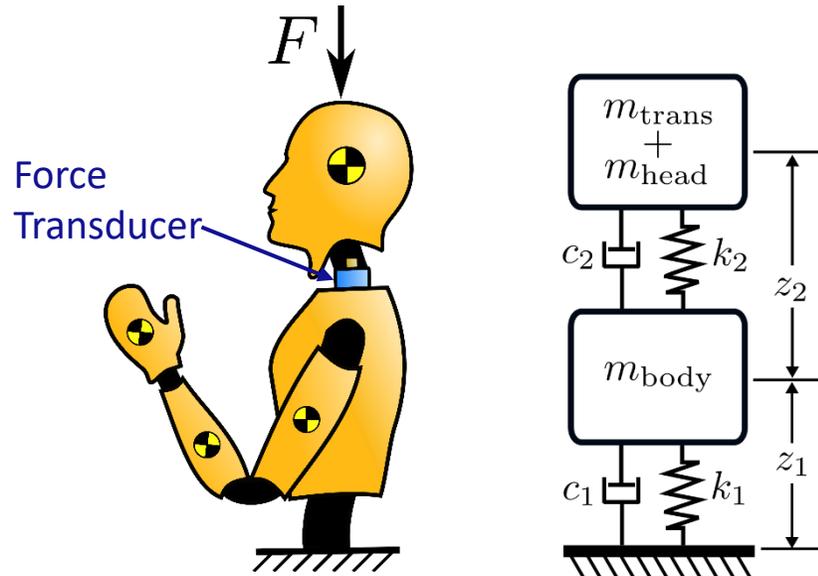

“It is thought that no apology is necessary for any proposition that promises to advance, be it ever so slightly, our capacity to measure forces.”

B. W. Dunn, *J. Franklin Institute*, 144 (1897)
